

FH can have severe consequences if left untreated.¹⁻³ Pediatric lipid screening is vital for improving early diagnosis⁴

Familial hypercholesterolemia (FH) exists in two forms and is characterized by **markedly elevated LDL-C levels from birth** that can lead to **premature** and **progressive ASCVD**.³⁻⁵

Heterozygous FH

LDL-C levels **>190 mg/dL** (adults) and **>160 mg/dL** (children or adolescents)⁶

Homozygous FH (rare)

LDL-C levels **≥400 mg/dL** (adults, adolescents, and children)^{6,7}

FH is currently **underdiagnosed** and undertreated in children⁴

According to a retrospective analysis, only **17.5%** of eligible healthy children from a geographically representative sample in the US underwent **lipid screening** (N=8,599,653)⁸

US pediatric lipid screening recommendations^{4,9}

All children between the ages of 9 and 11 years^{4,9}

At **2 years** of age if the child has:^{4,9}

A parent with total cholesterol **>240 mg/dL**

A family history of early-onset CAD

Underlying cardiac risk factors

Importance of conducting early pediatric lipid screening

Less severe forms of FH **may not be detected** until the first CV event occurs⁵

Most patients with untreated HoFH develop **overt atherosclerosis before 20 years** of age and generally **do not survive past 30 years of age**³

Pediatric lipid screening between the ages of 9 and 11 years may help **avoid confounding lipid changes** that transiently occur during puberty⁴

Don't let FH go undetected⁵

Screen kids for lipids⁹
